## Statistical modeling

Under exchangeability,

$$E\left(Y^{a}\mid\vec{L}=\vec{\ell}\right)=E\left(Y^{a}\mid A=a,\vec{L}=\vec{\ell}\right)$$

Under consistency,

$$E\left(Y^{a}\mid A=a,\vec{L}=\vec{\ell}\right)=E\left(Y\mid A=a,\vec{L}=\vec{\ell}\right)$$

To estimate, we have been taking the subgroup mean

$$\hat{E}(Y\mid A=a,\vec{L}=\vec{\ell}) = \frac{1}{n_{a,\vec{\ell}}} \sum_{i:A_i=a,\vec{L}_i=\vec{\ell}} Y_i$$

When subgroups are empty, we need a model. Example:

$$\hat{E}\left(Y\mid A=a,\vec{L}=\vec{\ell}\right)=\hat{\alpha}+A\hat{\beta}+\vec{L}'\hat{\vec{\gamma}}+A\vec{L}'\hat{\vec{\eta}}$$

# Parametric g-formula: Outcome modeling

- 1. Learn a model to predict Y given  $\{A, \vec{L}\}$
- 2. For each i, predict
  - $\blacktriangleright~\{A=1,\vec{L}=\vec{\ell}_i\},$  the conditional average outcome under treatment
  - $\blacktriangleright~\{A=0, \vec{L}=\vec{\ell}_i\}$  , the conditional average outcome under control
- 3. Take the difference for each unit
- 4. Average over the units

## G-formula: Data example

Estimate a model based on the true data

```
# A tibble: 10 \times 4
  а
                          race
                   sex
             <lgl> <chr> <fct>
  <chr>
 1 college
             FALSE Female Non-Hispanic Non-Black
 2 college
             FALSE Female Non-Hispanic Non-Black
 3 college TRUE Male
                          Non-Hispanic Non-Black
 4 college TRUE Male Non-Hispanic Non-Black
 5 no_college FALSE Male Hispanic
 6 no_college FALSE Female Hispanic
 7 no college TRUE Male Hispanic
 8 no college FALSE Female Hispanic
 9 no_college FALSE Male
                          Hispanic
10 no college FALSE Female Hispanic
```

### Predict values - control

Predict the counterfactuals when everybody is in the control group

```
# A tibble: 10 \times 3
   а
              sex
                     race
   <chr>
             <chr> <fct>
 1 no_college Female Non-Hispanic Non-Black
 2 no_college Female Non-Hispanic Non-Black
 3 no_college Male
                    Non-Hispanic Non-Black
 4 no_college Male
                    Non-Hispanic Non-Black
 5 no_college Male Hispanic
 6 no_college Female Hispanic
 7 no college Male Hispanic
 8 no_college Female Hispanic
 9 no college Male
                     Hispanic
10 no college Female Hispanic
```

## Predict values - treatment

Predict the counterfactuals when everybody is in the treatment group

```
# A tibble: 10 x 3
  а
       sex
                 race
   <chr> <chr> <chr> <fct>
 1 college Female Non-Hispanic Non-Black
 2 college Female Non-Hispanic Non-Black
 3 college Male Non-Hispanic Non-Black
 4 college Male Non-Hispanic Non-Black
5 college Male Hispanic
 6 college Female Hispanic
 7 college Male Hispanic
 8 college Female Hispanic
 9 college Male Hispanic
10 college Female Hispanic
```

# 1. Learn a model to predict Y given $\{A, \vec{L}\}$

# 2. Predict conditional average potential outcomes for every unit

# 3. Difference to estimate conditional average effects

```
conditional_average_effects <-
  conditional_average_outcomes %>%
  mutate(effect = yhat1 - yhat0)
```

## 4. Average over units

```
conditional_average_effects %>%
  select(yhat1, yhat0, effect) %>%
  summarize_all(.funs = mean)

# A tibble: 1 x 3
  yhat1 yhat0 effect
  <dbl> <dbl> <dbl> 1 0.427 0.164 0.263
```

# Recap. Parametric g-formula: Outcome modeling

- 1. Learn a model to predict Y given  $\{A, \vec{L}\}$
- 2. For each i, predict
  - $\blacktriangleright~\{A=1,\vec{L}=\vec{\ell}_i\},$  the conditional average outcome under treatment
  - $\blacktriangleright~\{A=0, \vec{L}=\vec{\ell}_i\},$  the conditional average outcome under control
- 3. Take the difference for each unit
- 4. Average over the units

## Extension 1: IPW Estimator

We can also estimate the causal effect using an IPW estimator

$$\pi_i = P(A_i = 1 \mid L = \ell_i)$$

- ▶ read about using glm() to estimate logistic regression
- when using predict(), search to find out how to predict probabilities

```
# turn outcome into 0/1
d <- d %>%
  mutate(a binary = a == "college")
# Estimate propensity score using logistic regression
propensity_model <- glm(a_binary ~ sex + race +</pre>
                           mom educ + dad educ +
                           log parent income +
                           log_parent_wealth +
                           test percentile,
                         family = binomial, data = d)
```

## IPW: Estimate the causal effect

Use the estimated propensty scores to calculate the ACE

$$\begin{split} \hat{E}(Y^1) &= \frac{1}{n} \sum_i \frac{A_i Y_i}{\hat{\pi}_i} \\ \hat{E}(Y^0) &= \frac{1}{n} \sum_i \frac{(1-A_i) Y_i}{1-\hat{\pi}_i} \end{split}$$

## IPW: Estimate the causal effect

## Extension 2: Conditional average effects

Modify the procedure above to estimate the average effect in subgroups defined by mom's education:

- 1. those with sex == Male
- 2. those with sex == Female

## Extension 2: Conditional average effects

Modify the procedure above to estimate the average effect in subgroups defined by mom's education:

- 1. those with sex == Male
- 2. those with sex == Female

#### One way to code it:

```
conditional_average_effects %>%
  group_by(sex) %>%
  select(sex, yhat0,yhat1,effect) %>%
  summarize_all(.funs = mean)
```

## Extension 2: Logistic regression

Since out outcome is binary, it's more appropriate to use logistic regression. Repeat the steps above with logistic regression

$$\log \left( \frac{\hat{P}\left(Y \mid A=a, \vec{L}=\vec{\ell}\right)}{1-\hat{P}\left(Y \mid A=a, \vec{L}=\vec{\ell}\right)} \right) = \hat{\alpha} + A\hat{\beta} + \vec{L}'\hat{\vec{\gamma}} + A\vec{L}'\hat{\vec{\eta}}$$

Helpful hints:

## Extension: Logistic regression

#### Fit a model

## Extension: Logistic regression

### Predict and summarize to estimate the average effect

```
d %>%
 mutate(yhat1 = predict(fit,
                         newdata = d %>%
                           mutate(a = "college"),
                         type = "response"),
         yhat0 = predict(fit,
                         newdata = d %>%
                           mutate(a = "no_college"),
                         type = "response"),
         effect = yhat1 - yhat0) %>%
  select(yhat1,yhat0,effect) %>%
  summarize all(.funs = mean)
```

```
# A tibble: 1 x 3
  yhat1 yhat0 effect
  <dbl> <dbl> <dbl> 1 0.406 0.165 0.241
```

# Recap. Parametric g-formula: Outcome modeling
